

# Confidential Hospital Records

## Problem Statement 3:

Confidential Hospital Records

A hospital wants to protect patient details such as patient ID, name, diagnosis, and prescription. Develop an application that encrypts the patient information before storing it and decrypts it only for authorized users.

Maintain confidentiality of patient data.

---

## Problem Statement 3:

### 1. Explanation

- The objective of this application is to protect confidential patient information such as Patient ID, Patient Name, Diagnosis, and Prescription.
- The application encrypts the patient details before storing them in a text file.
- In this program, the XOR encryption technique is used with a secret key.
- The encrypted information is stored in a file named hospital\_records.txt.
- Only an authorized user who provides the correct secret key can decrypt and view the original patient information.
- If an incorrect key is entered, access is denied.

### Working Process

1. Enter the Patient ID.
2. Enter the Patient Name.
3. Enter the Diagnosis.

4. Enter the Prescription.
5. Enter a secret encryption key.
6. Encrypt the patient information using XOR.
7. Store the encrypted information in hospital\_records.txt.
8. Enter the key to access the records.
9. If the key is correct, decrypt and display the patient details.
10. If the key is incorrect, unauthorized access is denied.

## 2. Input

Enter Patient ID: P101

Enter Patient Name: Anitha

Enter Diagnosis: Fever

Enter Prescription: Paracetamol

Enter Encryption Key (single character): H

Enter key to decrypt the record: H

## 3. C++ Code

```
#include <iostream>
#include <fstream> #include
<string> using
namespace std;

// XOR Encryption / Decryption Function string
encryptDecrypt(string text, char key)
{   for (int i = 0; i < text.length();
i++)
    {       text[i] = text[i]
^ key;
    }

    return text;
```

```

}

int main() {
    string patientID, name, diagnosis, prescription;
    char key;

    // Input patient details
    cout << "Enter Patient ID: ";
    getline(cin, patientID);

    cout << "Enter Patient Name: ";
    getline(cin, name);

    cout << "Enter Diagnosis: ";
    getline(cin, diagnosis);

    cout << "Enter Prescription: ";
    getline(cin, prescription);

    cout << "Enter Encryption Key (single character): ";
    cin >> key;

    // Encrypt patient information
    string encID =
    encryptDecrypt(patientID, key); string encName =
    encryptDecrypt(name, key); string encDiagnosis =
    encryptDecrypt(diagnosis, key); string encPrescription =
    encryptDecrypt(prescription, key);

    // Store encrypted data in file
    ofstream file("hospital_records.txt");
    if
    (!file)
    {
        cout << "Error opening file!" << endl;
        return 1;
    }

    file << encID << endl; file
    << encName << endl; file <<
    encDiagnosis << endl; file <<
    encPrescription << endl;

```

```

file.close();

cout << "\nPatient record encrypted and saved successfully!"
<< endl;

// Decryption
char decryptKey;

cout << "\nEnter key to decrypt the record: ";
cin >> decryptKey;

if (decryptKey == key)
{
    ifstream inputFile("hospital_records.txt");

    string encryptedID;
    string encryptedName;    string
    encryptedDiagnosis;
    string encryptedPrescription;

    getline(inputFile, encryptedID);
    getline(inputFile, encryptedName);    getline(inputFile,
    encryptedDiagnosis);
    getline(inputFile, encryptedPrescription);    inputFile.close();

    // Decrypt patient information    string
    decryptedID =
    encryptDecrypt(encryptedID, decryptKey);

    string decryptedName =
    encryptDecrypt(encryptedName, decryptKey);

    string decryptedDiagnosis =
    encryptDecrypt(encryptedDiagnosis, decryptKey);

    string decryptedPrescription =
    encryptDecrypt(encryptedPrescription, decryptKey);

    // Display decrypted information    cout
    << "\n--- Decrypted Patient Record ---"
    << endl;

```

```
        cout << "Patient ID   : "  
            << decryptedID << endl;  
  
        cout << "Patient Name : "  
            << decryptedName << endl;  
        cout << "Diagnosis   : "  
            << decryptedDiagnosis << endl;  
  
        cout << "Prescription : "  
            << decryptedPrescription << endl;  
    }   else  
    {  
        cout << "Unauthorized access! Invalid key."  
            << endl;  
    }  
  
    return 0;  
}
```

## 4. Output

```
main.cpp Run
16 {
38 // Ask for key to decrypt
39 char decryptKey;
40 cout << "\nEnter key to decrypt the note: ";
41 cin >> decryptKey;
42 // Check secret key
43 if (decryptKey == key)
44 {
45     ifstream inputFile("secure_notes.txt");
46     string encryptedData;
47     getline(inputFile, encryptedData);
48     inputFile.close();
49     // Decrypt the note
50     string decryptedNote =
51         encryptDecrypt(encryptedData, decryptKey);
52     cout << "\n--- Decrypted Note ---" << endl;
53     cout << decryptedNote << endl;
54 }
55 else
56 {
57     cout << "Unauthorized access! Invalid secret
58         key." << endl;
59 }
60 return 0;
61 }
```

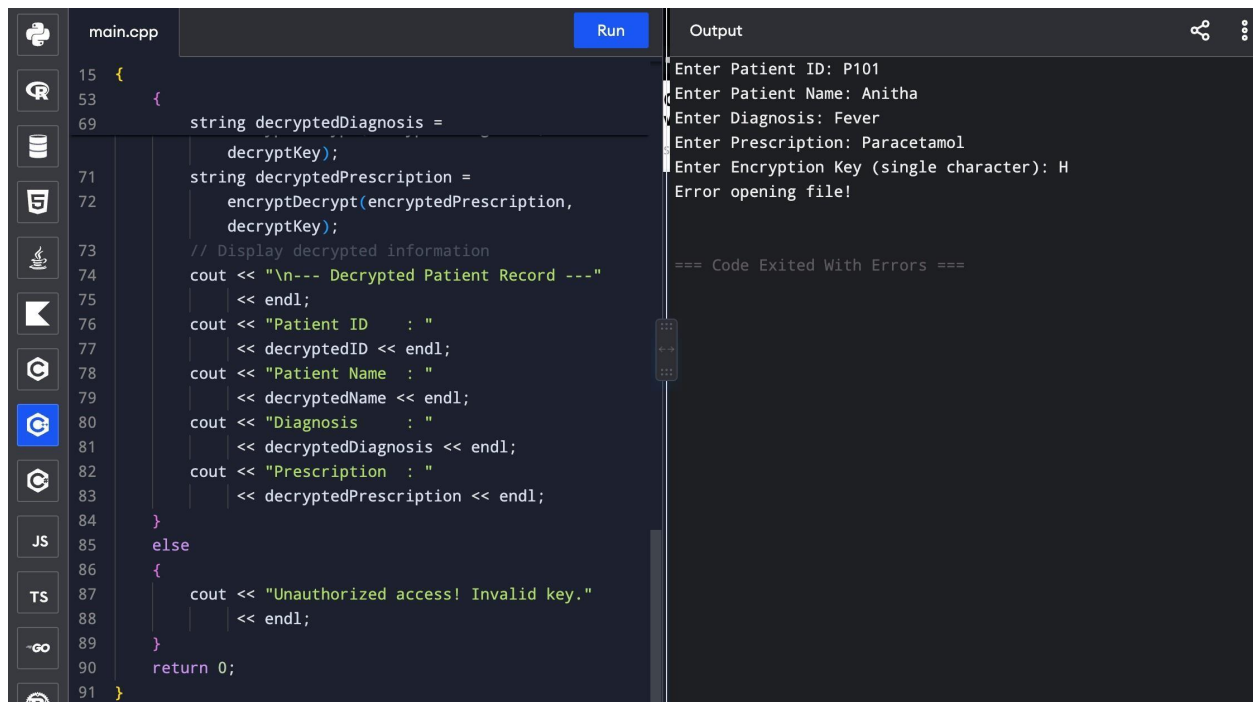

```
Output
Enter your confidential note: My project presentation is
tomorrow
Enter Secret Key (single character): S
Error opening file!

## 5. File Storage

- The encrypted patient information is stored in:
- hospital\_records.txt
- The original patient information is not directly stored as plain text.
- The information is converted into an encrypted form before being written to the file.

## 6. Security Features

- **Confidentiality:** Patient information is protected from unauthorized access.
- **Encryption:** XOR encryption is used to protect the data.
- **Secret Key:** A key is required to decrypt the records.
- **Access Control:** Incorrect keys are rejected.
- **Secure File Storage:** Encrypted patient data is stored in a text file.

## 7. Result

- Thus, the Confidential Hospital Records application was successfully implemented using C++. Patient ID, name, diagnosis, and prescription are encrypted before being stored in a file.
  - The original patient information can be viewed only by an authorized user with the correct secret key.
-
